The current feedback operational amplifier (CFOA or CFA) is a type of electronic amplifier whose inverting input is sensitive to current, rather than to voltage as in a conventional voltage-feedback operational amplifier (VFA). The CFA was invented by David Nelson at Comlinear Corporation, and first sold in 1982 as a hybrid amplifier, the CLC103.

Current Feedback Op Amps. Analog Devices high speed (> 50 MHz) current feedback op amps enable you to operate at higher speeds. Current feedback op amps traditionally have wider bandwidths and higher slew rates than voltage feedback amplifiers and feature constant bandwidth which is independent of gain. A current feedback op amp responds to an error current at its low-impedance negative input terminal, rather than an error voltage, and produces a corresponding output voltage.

current-feedback amplifiers (CFAs) have been in use for quite some time, there is a reluctance to view them in the same light as voltage-feedback amplifiers (VFAs). For instance, the gain-bandwidth curve of VFAs has a parallel

The Current-Feedback Op Amp: A High-Speed Building Block

The term “current feedback” refers to the internal operation of the op amp, not some new or exotic way of connecting the output back to the input. The standard gain arrangements are unchanged. Again, the inverting gain is remains $-R_f/R_{in}$, and the noninverting gain is remains $1+R_f/R_{in}$.

Current feedback amplifiers, Part 1 - Analog IC Tips

Current feedback amplifiers allow an easy resistive trim for frequency peaking that has no impact on the forward gain. Figure 7.3 shows this adjustment added to a non-inverting circuit.

Current Feedback Amplifier - an overview | ScienceDirect ...

The voltage feedback (VF) operational amplifier (op amp) is the most common type of op amp. The less well known current feedback (CF) op amp has been commercially available for about 20 years, but many designers are still uncertain about how to use them. Terminology is a confusing factor for many people.

Voltage Feedback vs. Current Feedback Op Amps

When the gain is increased to 10V/V or 20dB the voltage feedback amplifier's bandwidth will reduce to 10 MHz while the ideal current feedback amplifier's bandwidth does not change.

For a CFB op amp, the bandwidth is proportional to the feedback resistor. For every CFB op amp type, there is a recommended value of feedback resistor for maximum bandwidth, and increasing the size of the resistor beyond this value reduces the bandwidth. Fig 1: The gain of a CFB op amp is relatively flat up to the point of roll-off, unlike a VFB device which has a fixed gain-bandwidth product; CFB bandwidth is set by a simple resistor. Q: How does this affect the choice?

Current feedback amplifiers, Part 2 - Analog IC Tips

An Operational Amplifier, or op-amp for short, is fundamentally a voltage amplifying device designed to be used with external feedback components such as resistors and capacitors between its output and input terminals.

Operational Amplifier Basics - Op-amp tutorial

An operational amplifier, or op amp, generally comprises a differential-input stage with high input impedance, an intermediate-gain stage, and a push-pull output stage with a low output impedance...

How Do Operational Amplifiers Operate? | Electronic Design

Current feedback refers to any closed-loop configuration in which the error signal used for feedback is in the form of a current. A current feedback op amp responds to an error current at one of its input terminals, rather than an error voltage, and produces a corresponding output voltage.

Voltage-Feedback operational amplifiers (VFA op amps) allow circuit designers to swap gain for bandwidth. current-feedback op amps (CFAs) are simpler to use than VFAs, but do not offer...

What ' s The Difference Between Voltage-Feedback And Current ...

The op amp circuit is quite straightforward using few electronic components: a single feedback resistor from the output to the inverting input, and a resistor from the inverting input to the input of the circuit. The non-inverting input is taken a ground point.

Op Amp Gain - Explanation Calculation Equation ...

The noise current of the feedback resistor equals $i_n = \sqrt{4kT/R}$. Because of virtual ground at the negative input of the amplifier, $v_- = 0$ holds.. We therefore get for the root mean square (RMS) noise output voltage, $v_{n, rms} = i_n R$. A high feedback resistor is desirable because the transimpedance of the amplifier grows linearly with the resistance but the output noise only grows with the square root of the ...

Current-feedback amplifiers (CFA) do not have the traditional differential amplifier input structure, thus they sacrifice the parameter matching inherent to that structure.

This stability gives the op-amp the capacity to work in its linear (active) mode, as opposed to merely being saturated fully “ on ” or “ off ” as it was when used as a comparator, with no feedback at all. Because the op-amp ' s gain is so high, the voltage on the inverting input can be maintained almost equal to V_{in} . Let ' s say that our op-amp has a differential voltage gain of 200,000.
