Nitrogen application is an important agronomic measure affecting rice growth, yield and grain quality. This study investigated physicochemical properties and the structure of two rice varieties under three different nitrogen levels (0, 150 and 300 kg/ha) at one location in one year. The increasing nitrogen level decreased starch granule size.

In both years, the interaction of irrigation water amounts and nitrogen levels had a significant effect on the bulb yield. While the maximum yield had received at I 3 N 4 of 36.1 Mg ha ?1, the minimum of it had obtained at I 1 N 1 at 12.35 Mg ha ?1, which is about one-third of the maximum . As a result, in comparison to treatments that received enough water, over-irrigation was reduced yield at all of the applied nitrogen levels.

Dinitrogen oxide (N<sub>2</sub>O) is a greenhouse gas and also contributes to the depletion of stratospheric O<sub>3</sub>, resulting in increasing ultraviolet radiation. The direct impact of airborne nitrogen is due to toxic effects, eutrophication and acidification. Thresholds for eutrophication and soil acidification are discussed in Chapter 14.

Several harmful effects of nitrogen on human health include causing vitamin A shortages, decreasing function of the thyroid gland and decreasing the blood's ability to carry oxygen. These effects are seen when nitrogen occurs in an ion form, such as nitrite or nitrate. Decreased thyroid function and vitamin A shortages are both caused by nitrate. Nitrite reacts with hemoglobin in the blood, causing it to not carry oxygen as well.

Lodging is one of the constraints that limit wheat yields and quality due to the unexpected bending or breaking stems on wheat (*Triticum aestivum* L.) production worldwide. In addition to choosing lodging resistance varieties, husbandry practices also have a significant effect on lodging. Nitrogen management is one of the most common and efficient methods.

Effect of nitrogen level in number of leaves Data for number of leaves spelt out non-significant results. However, it shows some trend for different nitrogen levels indicating superiority of 300kg/ha and 250kg/ha over other treatment. 300kg/ha and 250kg/ha produced 20.125 number of leaves per plant, respectively (Table 1).

Exposure to the two most common nitrogen oxides, nitric oxide and nitrogen dioxide, can cause death, decreased fertility and genetic mutations. Tissue swelling, headaches and dizziness are common side effects when exposed to high levels of nitrogen oxides. Studies show that repeated exposure can lead to scarring.

Nitrogen fertilizer application and plant population levels had profound effects on crop phenology and grain yield of maize. Silking, tasseling days decreased and maturity, grain yield increased with increasing level of nitrogen (200 kg N/ha) whereas, these all traits increased with increasing level of plant population (83333 plants/ha).

Nitrogen in the Environment: Sources, Problems, and Management is the first volume to provide a holistic perspective and comprehensive treatment of nitrogen from field, to ecosystem, to treatment of urban and rural drinking water supplies, while also including a historical overview, human health impacts and policy considerations. It provides a worldwide perspective on nitrogen and agriculture. Nitrogen is one of the most critical elements required in agricultural systems for the production of crops for feed, food and fiber. The ever-increasing world population requires increasing use of nitrogen in agriculture to supply human needs for dietary protein. Worldwide demand for nitrogen will increase as a direct response to increasing population. Strategies and perspectives are considered to improve nitrogen-use efficiency. Issues of nitrogen in crop and human nutrition, and transport and transformations along the continuum from farm field to ground water, watersheds, streams, rivers, and coastal marine environments are discussed. Described are aerial transport of nitrogen from livestock and agricultural systems and the potential for deposition and impacts. The current status of nitrogen in the environment in selected terrestrial and coastal environments and crop and forest ecosystems and development of emerging technologies to minimize nitrogen impacts on the environment are addressed. The nitrogen cycle provides a framework for assessing broad scale or even global strategies to improve nitrogen use efficiency. Growing human populations are the driving force that requires increased nitrogen inputs. These increasing inputs into the food-production system directly result in increased livestock and human-excretory nitrogen contribution into the environment. The scope of this book is diverse, covering a range of topics and issues from furthering our understanding of nitrogen in the environment to policy considerations at both farm and national scales.

This book presents WHO guidelines for the protection of public health from risks due to a number of chemicals commonly present in indoor air. The substances considered in this review, i.e. benzene, carbon monoxide, formaldehyde, naphthalene, nitrogen dioxide, polycyclic aromatic hydrocarbons (especially benzo[a]pyrene), radon, trichloroethylene and tetrachloroethylene, have indoor sources, are known in respect of their hazardousness to health and are often found indoors in concentrations of health concern. The guidelines are targeted at public health professionals involved in preventing health risks of environmental exposures, as well as specialists and authorities involved in the design and use of buildings, indoor materials and products. They provide a scientific basis for legally enforceable standards.

Long-awaited second edition of classic textbook, brought completely up to date, for courses on tropical soils, and reference for scientists and professionals.
