 The five elements theory evolved from the study of various processes, functions, and phenomena of nature. The theory asserts substances can be divided into one of five basic elements: wood, fire, water, metal and earth, which contain their own specific characteristics and properties. Today, the five elements theory is still used as a tool for grouping objects, and as a method for analyzing changes of natural phenomena.

 In category theory, the concept of an element, or a point, generalizes the more usual set theoretic concept of an element of a set to an object of any category. This idea often allows restating of definitions or properties of morphisms given by a universal property in more familiar terms, by stating their relation to elements. Some very general theorems, such as Yoneda's lemma and the Mitchell embedding theorem, are of great utility for this, by allowing one to work in a context where these tran

 This theory was suggested around 450 BC, and it was later supported and added to by Aristotle.  Theory-elements are elementary empirical theories in two senses. First, they are the smallest set-theoretical entities that may have empirical claims associated with them. Second, more complex, non-elementary, "molecular" empirical theories are all built from theory-elements that are linked in specific ways (Ch. IV).

 The components of theory are concepts (ideally well defined) and principles. A concept is a symbolic representation of an actual thing - tree, chair, table, computer, distance, etc. Construct is the word for concepts with no physical referent - democracy, learning, freedom, etc. Language enables conceptualization.

Introduction to theory
