 The batch glass reactor are vessels that are used for several processes that include product mixing, chemical reactions, crystallization, and batch distillation. The batch reactors include combinations of multiple tanks, a cooling-system and storage tanks with agitators. These vessels are available in different sizes and will depend on the industries that they are used in.

2 Conversion and Reactor Sizing **2.1 Batch Reactor Design Equations** Conversion (of substance A) is defined as $X = \frac{\text{moles of A reacted}}{\text{moles of A fed}}$ - This can be rephrased mathematically as $X = \frac{N_0 - N}{N_0} = 1 - \frac{C_A}{C_{A0}}$ **0 The number of moles of A in the reactor after a conversion X has been achieved is** $N = N_0 (1 - X)$ By differentiating the above expression with respect to t and plugging it into the expression for the

All SBR designs should have a minimum of two basins to allow for redundancy, maintenance, high flows, and seasonal variations. Two basins allow for redundancy throughout the plant. If one basin is off line, the plant is still able to treat influent wastewater because of the equalization basin.

Batch reactors contain ports for injecting reactants and removing products, and can be outfitted with a heat exchanger or a stirring system. While batch reactors are generally of constant volume, some are designed to maintain a constant pressure by varying the reactor volume.

By sizing a chemical reactor we mean we're either deterring the reactor volume to achieve a given conversion or determine the conversion that can be achieved in a given reactor type and size. Here we will assume that we will be given $-r_A = f(X)$ and F_{A0} . In chapter 3 we show how to find $-r_A = f(X)$. Given $-r_A$ as a function of conversion, $-r_A = f(X)$, one can size any type of reactor.
