Linear Regression In a linear regression model the dependent variable Y is a random variable that satisfies $Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_p X_p + \epsilon$ where $X = (X_1, \dots, X_p)$ and is the "error" term. The linear model therefore implicitly assumes that $E[Y|X]$ is approximately linear in $X = (X_1, \dots, X_p)$. The input or independent variables, X_i , are numerical inputs

Linear regression models are often fitted using the least squares approach, but they may also be fitted in other ways, such as by minimizing the "lack of fit" in some other norm (as with least absolute deviations regression), or by minimizing a penalized version of the least squares cost function as in ridge regression (L 2-norm penalty) and lasso (L 1-norm penalty). Conversely, the least squares approach can be used to fit models that are not linear models.

The second half of the course will provide introduction to statistical modeling via introductory lectures on linear regression models, generalized linear regression models, nonparametric regression, and statistical computing. Throughout the course, real-data examples will be used in lecture discussion and homework problems.

Dept of Economics, University of St. Gallen. 2011. This paper offers an in-depth perspective on the DID approach and discusses some of the major issues with DID. It also provides a substantial amount of information on extensions of DID analysis including non-linear applications and propensity score matching with DID.

analogy to standard linear regression here: imagine that we want to fit the standard linear regression model to our data. Recall that this model hypothesizes that each bin of observed spike train data $n(t)$ of width Δt is generated according to $n(t) = \lambda \Delta t + \epsilon(t)$, where $\epsilon(t)$ is discrete Gaussian white noise.

Linear regression analysis is the most widely used of all statistical techniques: it is the study of linear, additive relationships between variables. Let Y denote the "dependent" variable whose values you wish to predict, and let X_1, \dots, X_k denote the "independent" variables from which you wish to predict it, with the value of variable X_i in period t (or in row t of the data set) denoted by X_{it} .
