Stability Modeling with SLOPE/W

Slope stability analysis. SLOPE/W is the leading slope stability software for soil and rock slopes. SLOPE/W can effectively analyze both simple and complex problems for a variety of slip surface shapes, pore-water pressure conditions, soil properties, and loading conditions. With this comprehensive range of features, SLOPE/W can be used to analyze almost any slope stability problem you will encounter in your geotechnical, civil, and mining engineering projects.

SLOPE/W

Students first model the slope stability of the 1973 slope by playing with the values of cohesion, internal friction and pore water pressure, and assume this pre-fill slope is stable. Students then add the fill layer from the 1983 profile, and select values for the cohesion, internal friction and pore water pressure that result in a factor of safety of less than one.

There is a steady state seepage file and two "child" SLOPE/W analyses. The two SLOPE/W analyses both point to their "parent" seepage analysis for detailed pore- water pressure information. The difference in the two SLOPE/W files is that, in one, the effects of added strength due to "suction" is included.

Using finite element computed stresses in SLOPE/W makes it possible to conduct a rigorous stability analysis using the same stress values resulting from the deformation analysis. In addition, you can use SIGMA/W stresses as the initial stress state for a dynamic earthquake analysis in QUAKE/W. Use SIGMA/W pore-water pressures in SLOPE/W or SEEP/W

slope stability analysis. This is due mainly to the fact that the effects of soil variability and vegetation are complex and difficult to quantify. Furthermore, the available slope stability analysis computer programs used in practice, which adopt conventional limit equilibrium methods, are unable to consider these factors.

Modelling the Stability of Natural Slopes

Scoops3D evaluates slope stability throughout a digital landscape represented by a digital elevation model (DEM). The program uses a three-dimensional (3D) method of columns limit-equilibrium analysis to assess the stability of many potential landslides (typically millions) within a user-defined size range.
