Thick Shell Plate A simply supported plate of equal side length is subjected to a normal pressure on the top face. Differences between thick shell formulations (elform 2, 3 and 5) can be studied. Example 2 from Introductory Manual for LS-DYNA Users by James M. Kennedy.

Thick shell form 5 in LS-DYNA is a layered 8 node brick element, with 4 nodes defining the bottom surface and 4 defining the top. For computational efficiency, each layer has one in-plane integration point. At least 2 layers are needed through the thickness, but there is no limit to the number of layers that may be defined.

The thermally thin shell has a constant temperature field over its thickness and expands only in length. The thermally thick shell, on the other hand, can map a temperature gradient across thickness, with the metal strip curving as a result of the change in thermal expansion across thickness.

- element does not distort unreasonably during the simulation - Used together with hourglass control type 8 , the type 16 shell will give the correct solution for warped geometries. [1] Formulation 6 with IRNXX set to -2 in *CONTROL_SHELL , while expensive, has been observed to give accurate springback response subsequent to a transient simulation involving large rotations, e.g., spinning blade.

In LS-DYNA, the eight-node solid thick shell element is still based on the Hughes-Liu and Belytschko-Lin-Tsay shells (Hallquist, 1998). A new eight-node solid element based on Liu, 1985, 1994 and 1998 is incorporated into LS-DYNA, intended for thick shell simulation.

When meshing adequately captures bending deformation, thick-shell elements are more flexible because of the additional shear deformation that is not captured through thin-shell formulation. Given pure-bending deformation, however, the thin-shell element is slightly more accurate, therefore the thick-shell element may be stiffer for coarser meshes.

2. The orientation of the material axes relative to the global axes throughout the analysis. * For a composite Shell or Thick Shell element this information is needed for all the through thickness integration points. The rules in LS-DYNA for calculating the material axes are complex as they can be defined via a number of different options.

When the Mooney-Rivlin Rubber material model is used with SHELL163 elements, the LS-DYNA code will automatically use a total Lagrangian modification of the Belytschko-Tsay formulation instead of using the formulation you specify via KEYOPT(1). This program-chosen formulation is required to address the special needs of the hyperelastic material.
